General Description

The AUR9713 is a high efficiency step-down DC-DC voltage converter. The chip operation is optimized using constant frequency, peak-current mode architecture with built-in synchronous power MOS switchers and internal compensators to reduce external part counts. It is automatically switching between the normal PWM mode and LDO mode to offer improved system power efficiency covering a wide range of loading conditions.

The oscillator and timing capacitors are all built-in providing an internal switching frequency of 1.5MHz that allows the use only small surface mount inductors and capacitors for portable product implementations. Additional features included integrated Soft Start (SS), Under Voltage Lock OUT (UVLO).

The device is available in adjustable output voltage versions ranging from 1V to 3.3V, and is able to deliver up to 1A.

The AUR9713 is available in TSOT-23-5 package.

Features

• High Efficiency Buck Power Converter
• Low Quiescent Current
• Output Current: 1A
• Adjustable Output Voltage from 1V to 3.3V
• Wide Operating Voltage Range: 2.5V to 5.5V
• Built-in Power Switches for Synchronous Rectification with High Efficiency
• Feedback Voltage: 600mV
• 1.5MHz Constant Frequency Operation
• Automatic PWM/LDO Mode Switching Control
• Thermal Shutdown Protection
• Low Drop-out Operation at 100% Duty Cycle
• No Schottky Diode Required

Applications

• Mobile Phone, Digital Camera and MP3 Player
• Headset, Radio and Other Hand-held Instrument
• Post DC-DC Voltage Regulation
• PDA and Notebook Computer

Application Information

The basic AUR9713 application circuit is shown in Figure 18, and external components selection is determined by the load current and is critical with the selection of inductor and capacitor values.

1. Inductor Selection

For most applications, the value of inductor is chosen based on the required ripple current with the range of 2.2µH to 4.7µH.

\[ \Delta I_L = \frac{1}{f \times L} V_{OUT}(1 - \frac{V_{OUT}}{V_{IN}}) \]

The largest ripple current occurs at the highest input voltage. Having a small ripple current reduces the ESR loss in the output capacitor and improves the efficiency. The highest efficiency is realized at low operating frequency with small ripple current. However, larger value inductors will be required. A reasonable starting point for ripple current setting is \( \Delta I_L = 40\% I_{MAX} \). For a maximum ripple current stays below a specified value, the inductor should be chosen according to the following equation:

\[
L = \left[ \frac{V_{OUT}}{f \times \Delta I_L (MAX)} \right] \left[ 1 - \frac{V_{OUT}}{V_{IN} (MAX)} \right]
\]

The DC current rating of the inductor should be at least equal to the maximum output current plus half the highest ripple current to prevent inductor core saturation. For better efficiency, a lower DC-resistance inductor should be selected.

2. Capacitor Selection

The input capacitance, \( C_{IN} \), is needed to filter the trapezoidal current at the source of the top MOSFET. To prevent large ripple voltage, a low ESR input capacitor sized for the maximum RMS current must be used. The maximum RMS capacitor current is given by:

\[ I_{RMS} = I_{OMAX} \times \left[ V_{OUT} \left( V_{IN} - V_{OUT} \right) \right]^{\frac{1}{2}} \]

\[ \frac{V_{IN}}{V_{IN}} \]

It indicates a maximum value at \( V_{IN} = 2V_{OUT} \), where \( I_{RMS} = I_{OUT}/2 \). This simple worse-case condition is commonly used for design because even significant deviations do not much relieve. The selection of \( C_{OUT} \) is determined by the Effective Series Resistance (ESR) that is required to minimize output voltage ripple and load step transients, as well as the amount of bulk capacitor that is necessary to ensure that the control loop is stable. Loop stability can be also checked by viewing the load step transient response as described in the following section. The output ripple, \( \Delta V_{OUT} \), is determined by:

\[ \Delta V_{OUT} \leq \Delta I_L \left[ ESR + \frac{1}{8 \times f \times C_{OUT}} \right] \]

The output ripple is the highest at the maximum input voltage since \( \Delta I_L \) increases with input voltage.

3. Load Transient

A switching regulator typically takes several cycles to respond to the load current step. When a load step occurs, \( V_{OUT} \) immediately shifts by an amount equal to \( \Delta I_{LOAD} \times ESR \), where ESR is the effective series resistance of output capacitor. \( \Delta I_{LOAD} \) also begins to charge or discharge \( C_{OUT} \) generating a feedback error signal used by the regulator to return \( V_{OUT} \) to its steady-state value. During the recovery time, \( V_{OUT} \) can be monitored for overshoot or ringing that would indicate a stability problem.

4. Output Voltage Setting

The output voltage of AUR9713 can be adjusted by a resistive divider according to the following formula:

\[ V_{OUT} = V_{REF} \times \left( 1 + \frac{R_1}{R_2} \right) = 0.6V \times \left( 1 + \frac{R_1}{R_2} \right) \]

The resistive divider senses the fraction of the output voltage as shown in Figure 17.
5. Efficiency Considerations

The efficiency of switching regulator is equal to the output power divided by the input power times 100%. It is usually useful to analyze the individual losses to determine what is limiting efficiency and which change could produce the largest improvement. Efficiency can be expressed as:

\[ \text{Efficiency} = 100\% - L_1 - L_2 - \ldots \]

Where \( L_1, L_2, \ldots \) are the individual losses as a percentage of input power.

Although all dissipative elements in the regulator produce losses, two major sources usually account for most of the power losses: \( V_{\text{IN}} \) quiescent current and \( I^2R \) losses. The \( V_{\text{IN}} \) quiescent current loss dominates the efficiency loss at very light load currents and the \( I^2R \) loss dominates the efficiency loss at medium to heavy load currents.

5.1 The \( V_{\text{IN}} \) quiescent current loss comprises two parts: the DC bias current as given in the electrical characteristics and the internal MOSFET switch gate charge currents. The gate charge current results from switching the gate capacitance of the internal power MOSFET switches. Each cycle the gate is switched from high to low, then to high again, and the packet of charge, \( dQ \), moves from \( V_{\text{IN}} \) to ground. The resulting \( \frac{dQ}{dt} \) is the current out of \( V_{\text{IN}} \) that is typically larger than the internal DC bias current. In continuous mode,

\[ I_{\text{GATE}} = f \times (Q_P + Q_N) \]

Where \( Q_P \) and \( Q_N \) are the gate charge of power PMOSFET and NMOSFET switches. Both the DC bias current and gate charge losses are proportional to the \( V_{\text{IN}} \) and this effect will be more serious at higher input voltages.

5.2 \( I^2R \) losses are calculated from internal switch resistance, \( R_{\text{SW}} \) and external inductor resistance \( R_L \). In continuous mode, the average output current flowing through the inductor is choppd between power PMOSFET switch and NMOSFET switch. Then, the series resistance looking into the LX pin is a function of both PMOSFET \( R_{\text{DS(ON)}} \) and NMOSFET \( R_{\text{DS(ON)}} \) resistance and the duty cycle (D):

\[ R_{\text{SW}} = R_{\text{DS(ON)}} \times D + R_{\text{DS(ON)}} \times (1 - D) \]

Therefore, to obtain the \( I^2R \) losses, simply add \( R_{\text{SW}} \) to \( R_L \) and multiply the result by the square of the average output current.

Other losses including \( C_{\text{IN}} \) and \( C_{\text{OUT}} \) ESR dissipative losses and inductor core losses generally account for less than 2% of total additional loss.

6. Thermal Characteristics

In most applications, the part does not dissipate much heat due to its high efficiency. However, in some conditions when the part is operating in high ambient temperature with high \( R_{\text{DS(ON)}} \) resistance and high duty cycles, such as in LDO mode, the heat dissipated may exceed the maximum junction temperature. To avoid the part from exceeding maximum junction temperature, the user should do some thermal analysis. The maximum power dissipation depends on the layout of PCB, the thermal resistance of IC package, the rate of surrounding airflow and the temperature difference between junction and ambient.

7. PCB Layout Considerations

When laying out the printed circuit board, the following checklist should be used to optimize the performance of AUR9713.

1) The power traces, including the GND trace, the LX trace and the VIN trace should be kept direct, short and wide.
2) Put the input capacitor as close as possible to the VIN and GND pins.
3) The FB pin should be connected directly to the feedback resistor divider.
4) Keep the switching node, LX, away from the sensitive FB pin and the node should be kept small area.
Typical Application

![Typical Application Circuit of AUR9713](image)

Note 3: \[ V_{OUT} = V_{REF} \times (1 + \frac{R_1}{R_2}) \]

When \( R_2 = 300\,\text{k}\Omega \) to \( 60\,\text{k}\Omega \), the \( I_{R2} = 2\,\mu\text{A} \) to \( 10\,\mu\text{A} \), and \( R_1 \times C_1 \) should be in the range between \( 3 \times 10^6 \) and \( 6 \times 10^6 \) for component selection.
