

## Description

The AL5887 is comprised of 36 programmable LED current channels each with internal 12-bit PWM for color and brightness control through SPI or I2C digital interface. AL5887 is ideal for up to 12 RGB LED modules lighting applications with 3 programmable banks (A, B, C) for software control of each color. An external resistor can set up the global output current of all 36 channels. Each channel current can digitally be configured up to 70mA under the thermal limitation of the package.

Features of the AL5887 are controlled via SPI/I2C digital interface. Using a dedicated pin INT\_SEL to select either SPI or I2C protocols. The AL5887 has a 30kHz, 12-bit PWM generator for each channel, as well as channel/module independent color mixing and brightness control registers to enable vivid LED effects with zero audible noise. Users can benefit from the device's ultra-low shutdown Iq Power Saving Mode and easy software programming.

The device operates over -40°C to +85°C ambient temperature range. The AL5887 is available in W-QFN6060-52/SWP (Type A1) package.

## Features

- Input Voltage: 2.7V to 5.5V
- 36 Precision LED Current Sinks
  - OUT Pins Voltage Max. 5.5V
  - A Maximum of up to 70mA per Channel Current
  - Device to Device and Channel to Channel Current Accuracy: < 2% at 7mA to 70mA, and < 3.5% at 1mA to 7mA
  - 12-Bit (4096 Steps), 30kHz PWM Generator Integrated for Each Channel
  - PWM Phase Shifting
  - 6-Bit Global Current Dimming
  - Independent Color-Mixing Register per Channel
  - Independent Brightness Control Register per RGB Module
  - Optional Logarithmic- or Linear-Scale Brightness Control
  - Three Programmable Banks (A, B, C)
- Serial Digital Interface (I2C/SPI)
  - Support 400kHz I2C Interface (Default)
  - Two External Hardware Address Pins Allow Connecting up to Four Devices (I2C Only)
  - 4MHz SPI Compatible Digital Interface (INT\_SEL Pin = HIGH)
  - Broadcast Slave Address Allows Configuring Multiple Devices Simultaneously
  - Auto-Increment Allows Writing or Reading Consecutive Registers Within One Transmission
- Diagnosis and Protections
  - Open Drain Fault Pin for Fault Indication
  - Individual LED Channel Open/Short Detection
  - Pre-UVLO Warning & Undervoltage Lockout (UVLO)
  - Overtemperature Protection (OTP) with Pre-OTP Warning
  - Digital POR Indicator
  - Individual Channel Fault Masking
- Ultra-Low Quiescent Current:
  - Shutdown Mode: 1µA (Max.) When EN Low > 25ms
  - Power-Saving Mode: 15µA (Max.) When EN High and All LEDs Off for > 30ms
- **Totally Lead-Free & Fully RoHS Compliant (Notes 1 & 2)**
- **Halogen and Antimony Free. "Green" Device (Note 3)**
- **For automotive applications requiring specific change control (i.e. parts qualified to AEC-Q100/101/104/200, PPAP capable, and manufactured in IATF 16949 certified facilities), please [contact us](https://www.diodes.com/quality/product-definitions/) or your local Diodes representative.**

<https://www.diodes.com/quality/product-definitions/>

- Notes:
1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS), 2011/65/EU (RoHS 2) & 2015/863/EU (RoHS 3) compliant.
  2. See <https://www.diodes.com/quality/lead-free/> for more information about Diodes Incorporated's definitions of Halogen- and Antimony-free, "Green" and Lead-free.
  3. Halogen- and Antimony-free "Green" products are defined as those which contain <900ppm bromine, <900ppm chlorine (<1500ppm total Br + Cl) and <1000ppm antimony compounds.

Orderable Part Number	Package	Body Size
AL5887JAZW52-13	W-QFN6060-52/SWP (Type A1)	6mm x 6mm

**Typical Applications Circuit**

1) For I2C Interface

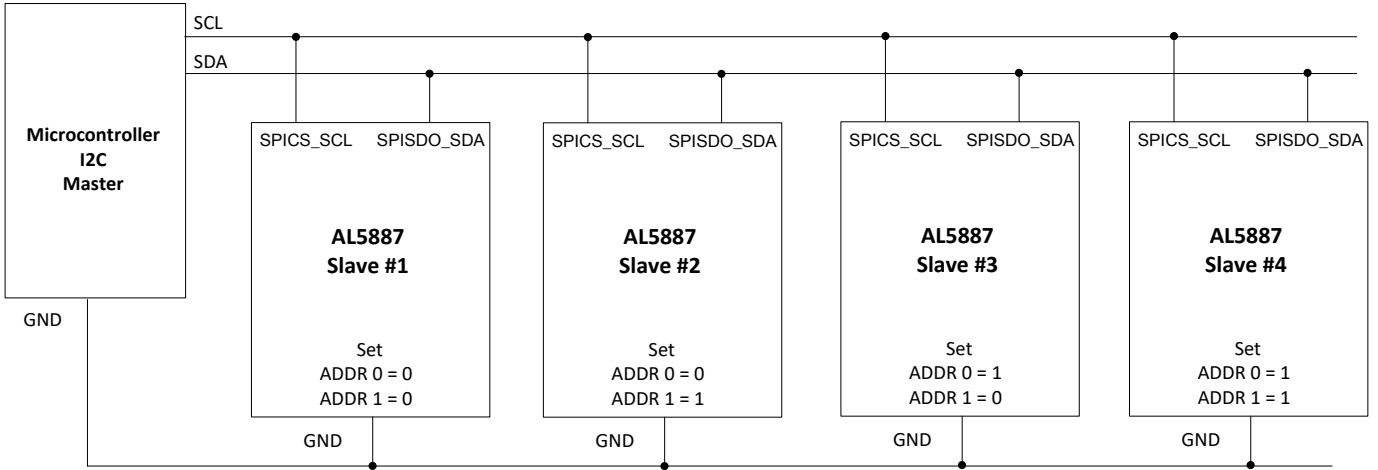

2) For SPI Interface

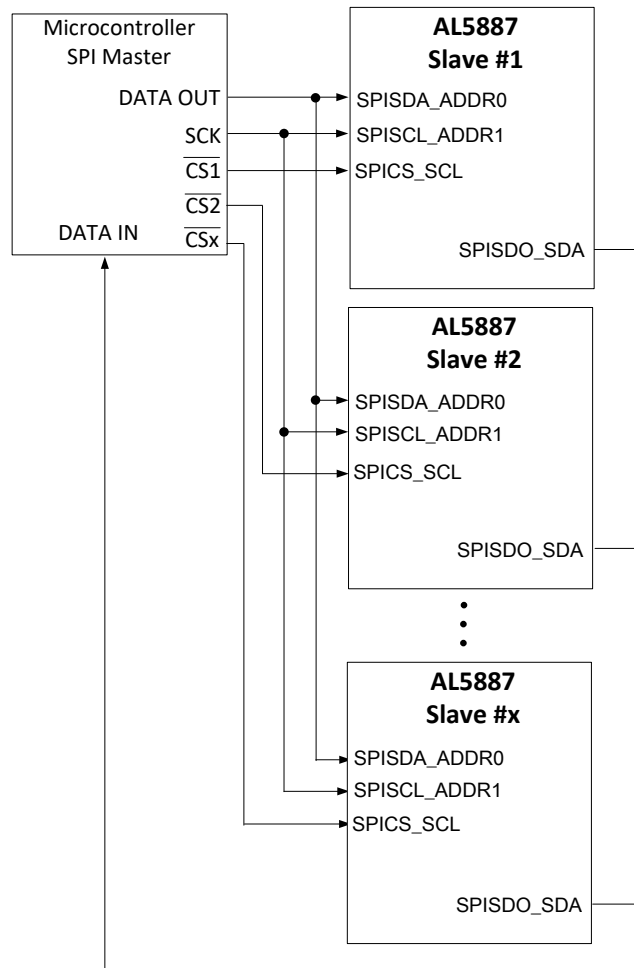

**Typical Applications Circuit** (continued)

3) Four AL5887 connected together with external hardware pins setup

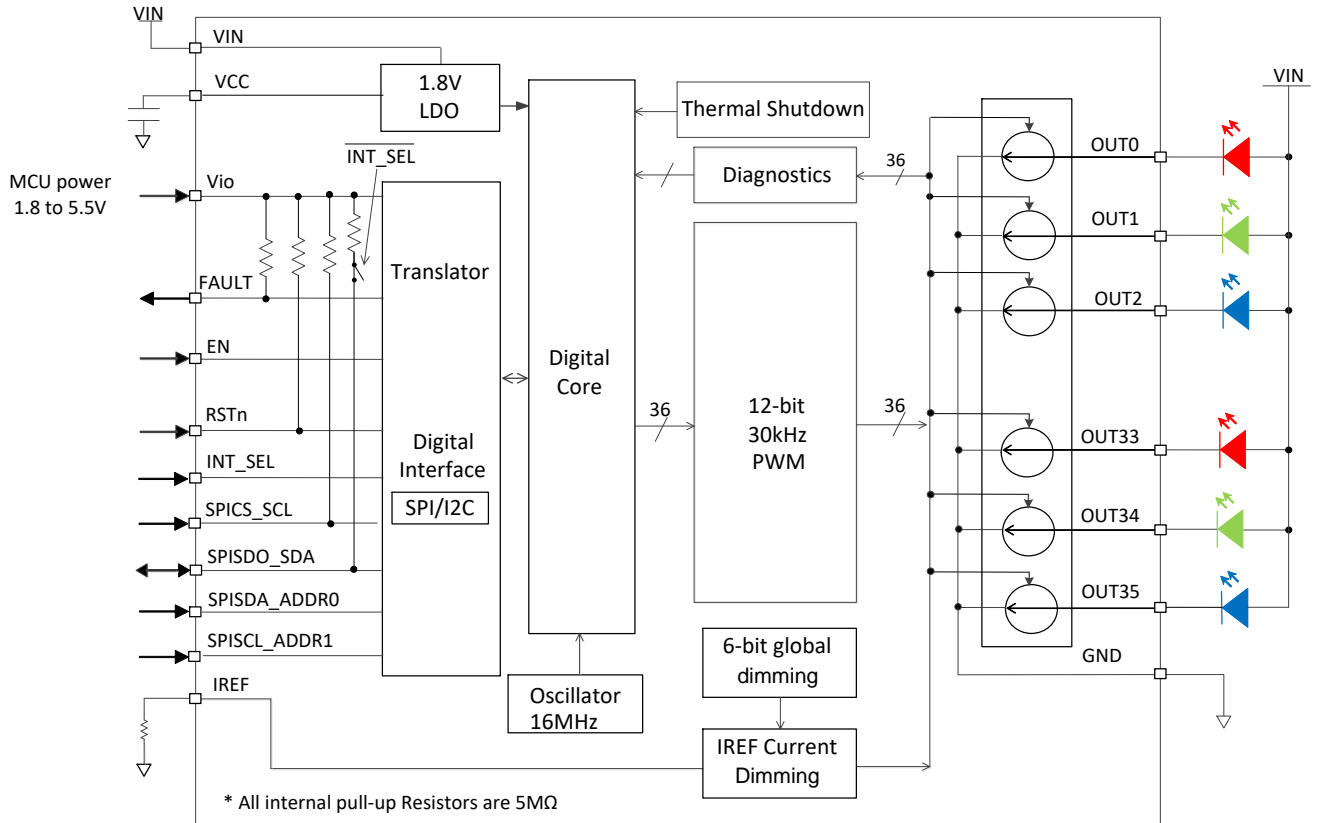

4) AL5887 (SPI interface) connected in parallel

## Pin Descriptions

Pin Name	Pin Number	Type	Function
OUT0 to OUT5	1 to 6	O	Current sink output for LED 0 to LED 5
OUT6 to OUT17	8 to 19	O	Current sink output for LED 6 to LED 17
OUT18 to OUT29	21 to 32	O	Current sink output for LED 18 to LED 29
OUT30 to OUT35	34 to 39	O	Current sink output for LED 30 to LED 35
Vio	40	I	Input power from MCU power rail
FAULT	41	O	Analog output with open drain internal pull up 5MΩ resistor to Vio for fault indication
SPISDO_SDA	42	I/O	INT_SEL = HIGH, SPI master input slave output, serial data line INT_SEL = LOW, I2C Data line If not used, this pin must be connected to GND or VIN. (Default = HIGH for I2C)
SPICS_SCL	43	I	INT_SEL = HIGH, SPI active low chip select INT_SEL = LOW, I2C bus clock line If not used, this pin must be connected to GND or VIN. (Default = HIGH)
SPISDA_ADDR0	44	I	INT_SEL = HIGH, SPI master output slave input, serial data line INT_SEL = LOW, I2C slave-address selection pin This pin must not be left floating. (Default = LOW)
SPISCL_ADDR1	45	I	INT_SEL = HIGH, SPI serial clock line from SPI master (FPGA) INT_SEL = LOW, I2C slave-address selection pin This pin must not be left floating. (Default = LOW)
IREF	47	O	Connect an external resistor to regulate all channel output current.
INT_SEL	48	I	Selects the required communication interface. INT_SEL = LOW selects I2C and INT_SEL = HIGH selects SPI. This pin must not be left floating. (Default = LOW)
VCC	49	O	Internal LDO 1.8V output pin, this pin must be connected to a 1μF capacitor to GND.
RSTn	50	I	Resets digital interface only but retains other register values if pulled down for time between 1ms to 20ms. Resets all register values if pulled down for time more than 20ms. Needs to be pulled high for powering up the internal digital block. (Default = HIGH)
EN	51	I	Active low to shut down the chip. (Default = LOW)
VIN	52	Power	Power supply
GND	7, 20, 33, 46	GND	Ground
—	Thermal Exposed Pad	GND	Thermal exposed pad also serves as a ground for the device.

**Functional Block Diagram**

**Absolute Maximum Ratings** (@T<sub>A</sub> = +25°C, unless otherwise specified.) (Note 4)

Symbol	Parameter	Rating	Unit
V <sub>IN</sub>	Input Voltage, Voltage Relative to GND	-0.3 to 6	V
I <sub>OUTx</sub>	OUTx Output Current	160	mA
V <sub>OUTx</sub> , EN, FAULT, RSTn, V <sub>io</sub> , INT_SEL, SPICS_SCL, SPISDO_SDA, SPISDA_ADDR0, SPISCL_ADDR1, IREF	High-Voltage Pins	-0.3 to 6V	V
VCC	Low-Voltage Pins	-0.3 to 2V	V
T <sub>J</sub>	Junction Temperature	-40 to +150	°C
T <sub>STG</sub>	Storage Temperature	-65 to +150	°C
ESD	HBM	2000	V
	CDM	1000	V

Note: 4. Stresses greater than those listed under *Absolute Maximum Ratings* can cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to *Absolute Maximum Ratings* for extended periods can affect device reliability. Semiconductor devices are ESD sensitive and may be damaged by exposure to ESD events. Suitable ESD precautions should be taken when handling and transporting these devices.

## Functional Descriptions

### 1. General Operation

One of the I2C or SPI protocols can be selected using INT\_SEL pin. Using I2C/SPI interface, AL5887 controls LED's color and brightness through 4 primary mechanisms:

1. Use RSET to set full range for LED current I<sub>MAX</sub> (up to 70mA).
2. Set I<sub>MAX</sub> by using 6-bit global dimming register, which is termed as LED GLOBAL DIMMING in the registers map.
3. Set color/brightness registers for LED color and brightness (see *Registers Map Description*).
4. Further select various dimming and protection features described in *Registers Map Description*.

### 2. Feature Description

#### 2.1 Each Channel PWM Control

The AL5887 device is designed with independent color mixing and brightness control, which makes it easier to achieve the RGB LED color effects needed. With the inputs of the color-mixing register and the brightness-control register, the final PWM generator output for each channel is 12-bit resolution and 30kHz dimming frequency, which helps achieve a smooth dimming effect and eliminates audible noise. See Figure 7.

For example, yellow color has the red, green and blue components as 255, 255 and 0 respectively. So to get the color yellow for the first RGB LED module, the color registers at the addresses 14h, 15h and 16h need to be configured with the values 255, 255 and 0 respectively. And then the brightness register for first RGB LED module at the address 8h can be configured based on the amount of brightness needed, 255 being the maximum brightness.

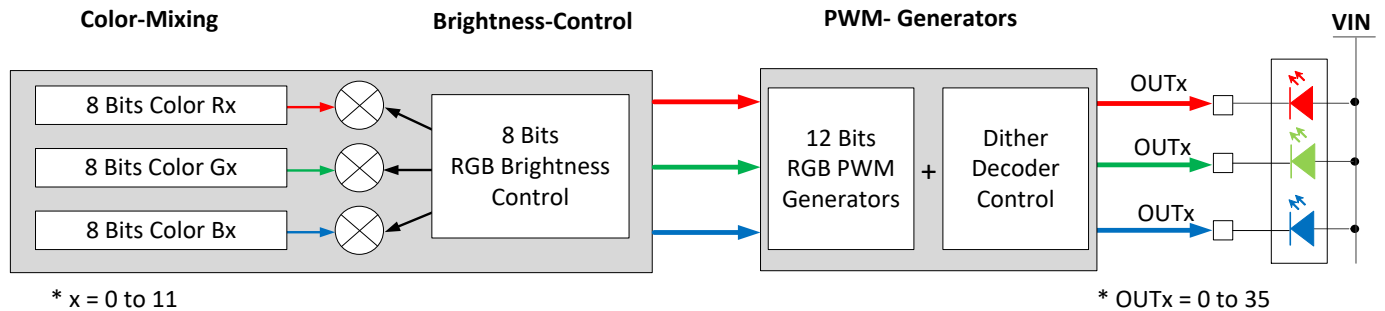

Figure 7. PWM Control Scheme for Each Channel

#### 2.1.1 Independent Color Mixing Per RGB LED Module

Each output channel has its own individual 8-bit color-setting register (OUT<sub>x</sub>\_COLOR). The device allows every RGB LED module to achieve > 16 million (256 × 256 × 256) color-mixing.

#### 2.1.2 Independent Brightness Control per RGB LED Module

When color is fixed, the independent brightness-control is used to achieve accurate and flexible dimming control for every RGB LED module.

##### 2.1.2.1 Brightness-Control Register Configuration

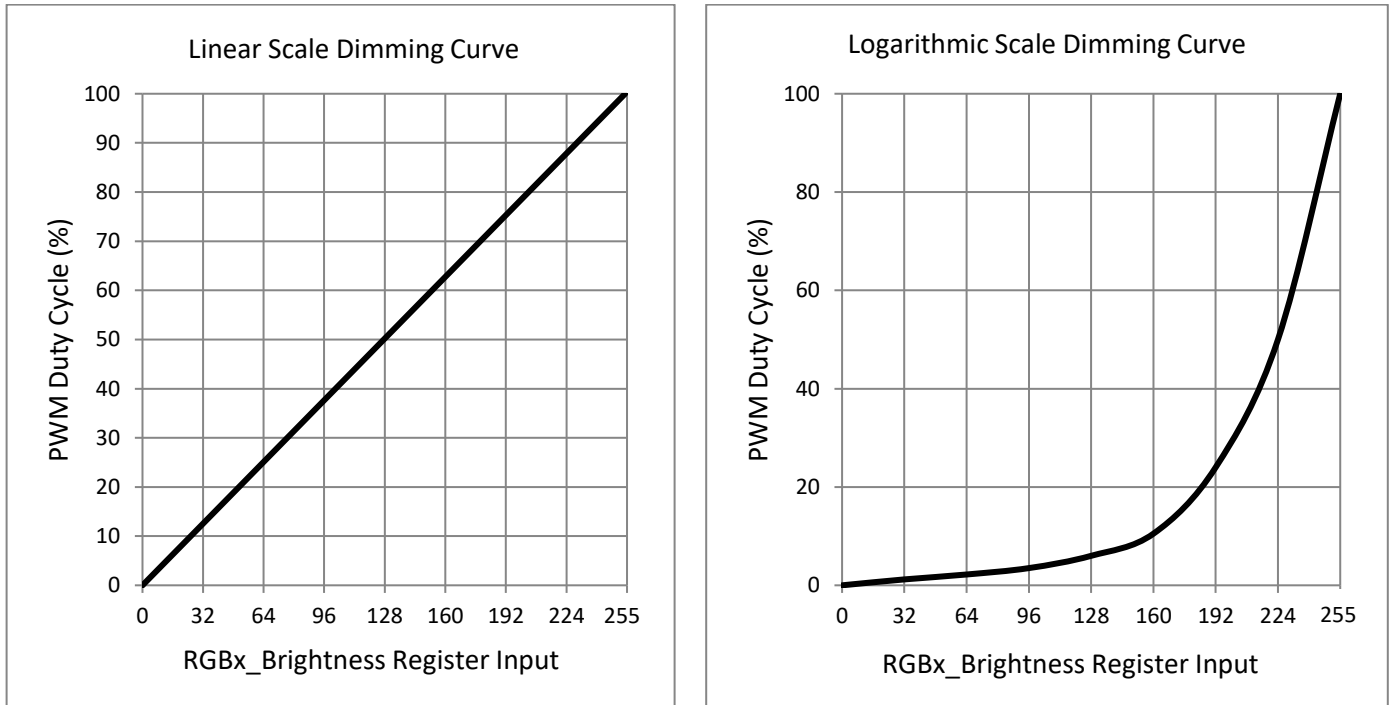

Every three consecutive output channels are assigned to their respective brightness-control register (RGB<sub>x</sub>\_BRIGHTNESS). For example, LED0, LED1, and LED2 are assigned to RGB0\_BRIGHTNESS, so it is recommended to connect the RGB LEDs in the sequence as shown in Table 1. The AL5887 device allows 256-step brightness control for each RGB LED module, which helps achieve a smooth dimming effect.

Keeping FFh (default value) in the RGB0\_BRIGHTNESS register results in 100% dimming brightness. With this setting, the users can just configure the color mixing register by channel to achieve the target dimming effect in a single-color LED application.

**Functional Descriptions** (continued)

**2.1.2.2 Logarithmic- or Linear-Scale Brightness Control**

For human-eye-friendly visual performance, a logarithmic-scale dimming curve is usually implemented in LED drivers. However, for RGB LEDs, if using a single register to achieve both color mixing and brightness control, color distortion can be observed easily when using a logarithmic scale. The AL5887 device, with independent color-mixing and brightness-control registers, implements the logarithmic scale dimming control inside the brightness control function, which solves the color distortion issue effectively (See Figure 8). Also, the AL5887 device allows users to configure the dimming scale either logarithmically or linearly through the global Log\_Scale\_EN register bit. If a special dimming curve is desired, using the linear scale with software correction is the most flexible approach.

**Figure 8. Logarithmic vs Linear Dimming Curve**

**2.1.3 12-Bit, 30kHz PWM Generator per Channel**

With the inputs of the color mixing and the brightness control, the final output PWM duty cycle is defined as the product obtained by multiplying the color-mixing register value by the related brightness-control register value. The final output PWM duty cycle has 12 bits of control resolution, which is achieved by a 9 bits of pure PWM resolution and 3 bits of dithering digital control. The AL5887 device allows the users to enable or disable the dithering function through the PWM\_Dithering\_EN register. When enabled (default), the output PWM duty-cycle resolution is 12 bits. When disabled, the output PWM duty-cycle resolution is 9 bits. More details about dithering is mentioned in the following paragraph.

When 3-bit dithering is enabled, dither effect is generated with 8 ( $2^3 = 8$ ) possible dither values: “0”, “1”, “2”,...“7”, where 0 means no dithering; “1” means every 8<sup>th</sup> PWM pulse is made 1 LSB longer to increase the final average duty cycle by 1 LSB/8 (duty cycle is termed as DT); “2” means in every group of 8 PWM pulses, the 7<sup>th</sup> and 8<sup>th</sup> PWM pulses are both made 1 LSB longer to increase DT by 2 LSB/8, etc. AL5887 uses 512 clocks in a 100% PWM DT period to achieve 9-bit pure PWM resolution ( $2^9 = 512$ ), thus 1 LSB PWM DT is 1/512. Therefore dither value “1” adds  $1/(8 \times 512) = 0.0244\%$  additional DT to pure PWM DT. For example, combining with dither value “1”, the pure PWM DT of 25% will actually generate DT = 25.0244% for LED current regulation; while with dither value “2”, pure PWM DT of 25% will actually generate DT = 25.05%. Though AL5887 pure PWM resolution is  $1/512 = 0.195\%$ , the 3-bit dither scheme enhances PWM resolution to 0.0244%.

## Functional Description (continued)

### 2.1.4 PWM Phase-Shifting

A PWM phase-shifting scheme allows delaying the time when each LED driver is active. When the LED drivers are not activated simultaneously, the peak load current from the pre-stage power supply is significantly decreased. The scheme also reduces input-current ripple and ceramic-capacitor audible ringing. LED drivers are grouped into three different phases.

- Phase 1 - The rising edge of the PWM pulse is fixed. The falling edge of the pulse is changed when the duty cycle changes. Phase 1 is applied to LED0, LED3, ..., LED[3 × (n – 1)].
- Phase 2 - The middle point of the PWM pulse is fixed. The pulse spreads in both directions when the PWM duty cycle is increased. Phase 2 is applied to LED1, LED4, ..., LED[3 × (n – 1) + 1].
- Phase 3 - The falling edge of the PWM pulse is fixed. The rising edge of the pulse is changed when the duty cycle changes. Phase 3 is applied to LED2, LED5, ..., LED[3 × (n – 1) + 2].

### 2.2 LED Bank Control

For most LED-animation effects, like blinking and breathing, all the RGB LEDs have the same lighting pattern. Instead of controlling the individual LED separately, which occupies the microcontroller resources heavily, the AL5887 device provides an easy coding approach, the LED bank control. Each channel can be configured as either independent control or bank control through the LEDx\_Bank\_EN register. When LEDx\_Bank\_EN = 0 (default), the LED is controlled independently by the related color-mixing and brightness-control registers. When LEDx\_Bank\_EN = 1, the AL5887 device drives the LED in LED bank-control mode. The LED bank has its own independent PWM control scheme, which is the same structure as the PWM scheme of each channel. When a channel configured as LED bank-control mode, the related color mixing and brightness control is governed by the bank control registers (BANK\_A\_COLOR, BANK\_B\_COLOR, BANK\_C\_COLOR, and BANK\_BRIGHTNESS) regardless of the inputs on its own color-mixing and brightness-control registers.

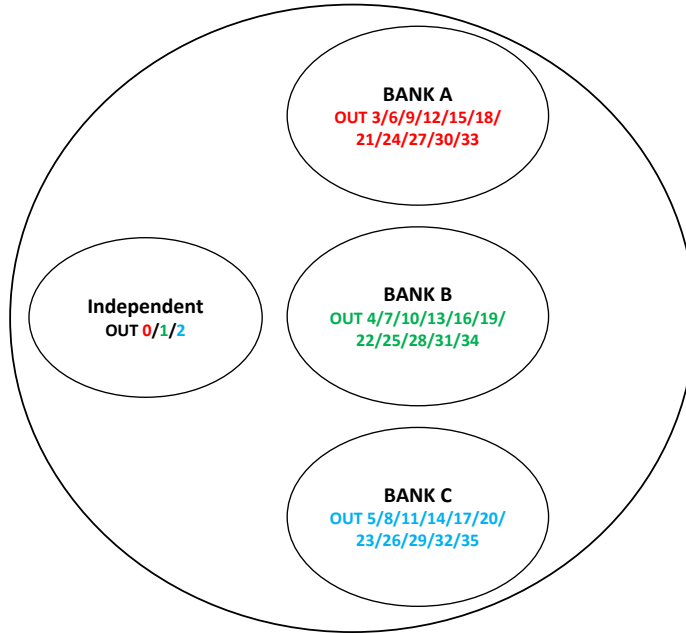

**Table 1. Bank Number and RGB Number Assignment**

Out Number	Bank Number	RGB Module Number	Out Number	Bank Number	RGB Module Number
OUT0	Bank A	RGB0	OUT18	Bank A	RGB6
OUT1	Bank B		OUT19	Bank B	
OUT2	Bank C		OUT20	Bank C	
OUT3	Bank A	RGB1	OUT21	Bank A	RGB7
OUT4	Bank B		OUT22	Bank B	
OUT5	Bank C		OUT23	Bank C	
OUT6	Bank A	RGB2	OUT24	Bank A	RGB8
OUT7	Bank B		OUT25	Bank B	
OUT8	Bank C		OUT26	Bank C	
OUT9	Bank A	RGB3	OUT27	Bank A	RGB9
OUT10	Bank B		OUT28	Bank B	
OUT11	Bank C		OUT29	Bank C	
OUT12	Bank A	RGB4	OUT30	Bank A	RGB10
OUT13	Bank B		OUT31	Bank B	
OUT14	Bank C		OUT32	Bank C	
OUT15	Bank A	RGB5	OUT33	Bank A	RGB11
OUT16	Bank B		OUT34	Bank B	
OUT17	Bank C		OUT35	Bank C	

With the bank control configuration, the AL5887 device enables users to achieve smooth and live LED effects globally with an ultra-simple software effort.

For example (as shown in Figure 9), say if we want to configure RGB0 in independent mode and rest of RGB1 to RGB11 in BANK mode, we can do that by configuring LED\_CONFIG0 register to FEh and LED\_CONFIG1 register to 0Fh. By doing this, the RGB0 module operating in independent mode will be using RGB0\_BRIGHTNESS for brightness and R0\_COLOR, G0\_COLOR and B0\_COLOR for R, G, and B colors respectively, while the other RGB modules in bank mode would use BANK\_BRIGHTNESS for brightness and BANK A, BANK B, and BANK C for R, G and B colors respectively.

**Functional Description** (continued)

**Figure 9. Bank PWM Control Example**

**2.3 Automatic Power-Save Mode**

When all the LED outputs are inactive, the AL5887 device is able to enter power-save mode automatically, thus lowering idle-current consumption down to 25µA (maximum). Automatic power-save mode is enabled when register bit Power\_Save\_EN = 1 (default) and all the LEDs are off (both color and brightness registers = 00H) for a duration of > 30ms. Almost all analog blocks are powered down in power-save mode. If any I2C/SPI command to the device occurs, the AL5887 device returns to NORMAL mode.

**2.4 Protection Features**

**2.4.1 LED Open-Circuit Diagnostics**

The AL5887 integrates LED open-circuit diagnostics to allow users to monitor LED status real time. The device monitors OUTx voltage to determine if there is any open-circuit failure.

If the voltage  $V_{OUTx}$  for any of the channels goes below threshold  $V_{OPEN\_th\_rising}$  and if the open persists for more than  $t_{FAULT\_WAIT}$ , the AL5887 pulls the FAULT pin low to report fault and also sets flag register Open\_Fault\_CHx and FLAG\_OPEN to 1. Once the open-circuit failure is removed, the controller needs to send CLR\_FAULT to clear the FLAG\_OPEN after fault removal. The fault delay is decided based on below table.

**Table 2. Fault Wait Time**

FW1	FW0	t <sub>FAULT_WAIT</sub>
0	0	8 PWM clock count
0	1	16 PWM clock count
1	0	24 PWM clock count
1	1	32 PWM clock count

**2.4.2 LED Short-Circuit Diagnostics**

AL5887 monitors voltage difference between supply (VIN) and OUTx to determine if there is any short-circuit failure. If the difference voltage ( $V_{IN} - V_{OUTx}$ ) for any of the channel falls below threshold ( $V_{SC\_th\_rising}$ ) and if the short persists for more than  $t_{FAULT\_WAIT}$ , the AL5887 pulls the FAULT pin low to report fault and also sets flag register Short\_Fault\_CHx and FLAG\_SHORT to 1. The MCU should turn off the channel that detects a short fault to avoid overstressing device. Once the short-circuit failure is removed, the controller needs to send CLR\_FAULT to clear the FLAG\_SHORT after fault removal.

---

## Functional Description (continued)

---

### 2.4.3 Pre-OTP Warning & Thermal Shutdown

The AL5887 has pre-thermal warning threshold of +145°C (typical) and thermal shutdown threshold of +160°C (typical)

When the AL5887 junction temperature rises above pre-thermal warning threshold of +145°C (typical) and if it persists for more than 33μs, the device reports pre-thermal warning by pulling FAULT pin low, and sets the flag register FLAG\_PREOTP to 1. The device releases Pre-OTP warning once the temperature goes below +125°C. Once the fault is removed, the controller needs to send CLR\_FAULT to clear the flag register after fault removal.

The AL5887 device also implements a thermal shutdown mechanism to protect the device from damage due to overheating. When the junction temperature further rises to +160°C (typical), the device shuts down all output drivers and pulls the FAULT pin low. The AL5887 device releases thermal shutdown when the junction temperature of the device is reduced to +140°C (typical).

### 2.4.4 Pre-UVLO Warning

The AL5887 provides Pre-UVLO feature that warns the MCU about supply (VIN) being low and soon UVLO might be triggered. When VIN goes below Pre-UVLO- threshold and if it persists for more than 33μs, FAULT pin is pulled low and the flag register FLAG\_PREUVLO is set to 1. The device releases Pre-UVLO warning once the VIN goes above Pre-UVLO+ threshold. Once the fault is cleared, the controller needs to send CLR\_FAULT to clear the flag register after fault removal.

### 2.4.5 UVLO

The AL5887 device has an internal comparator that monitors the voltage at VIN. When VIN is below UVLO-, reset is active and the AL5887 device is in the INITIALIZATION state. When VIN supply goes below the UVLO- threshold, FAULT pin is pulled low to indicate the fault.

### 2.4.6 Digital POR Indicator

The AL5887 device has a digital bit FLAG\_POR to indicate the power on reset. The default value of this bit is high to indicate the power on reset of digital block. The controller can set CLR\_POR during the start of the operation to reset FLAG\_POR so that the next power on reset to digital block can be captured.

### 2.4.7 Fault Masking

Open\_Mask\_CHx prevents the output open-circuit fault of individual channels from being reported to FAULT pin while Open\_Mask prevents any of the channels open fault from being reported to FAULT pin.

Short\_Mask\_CHx prevents the output short-circuit fault of individual channels from being reported to FAULT pin while Short\_Mask prevents any of the channels short fault from being reported to FAULT pin.

Pre\_OTP\_Mask prevents the Pre\_OTP fault from being reported to FAULT pin.

Pre\_UVLO\_Mask prevents the Pre\_UVLO fault from being reported to FAULT pin.

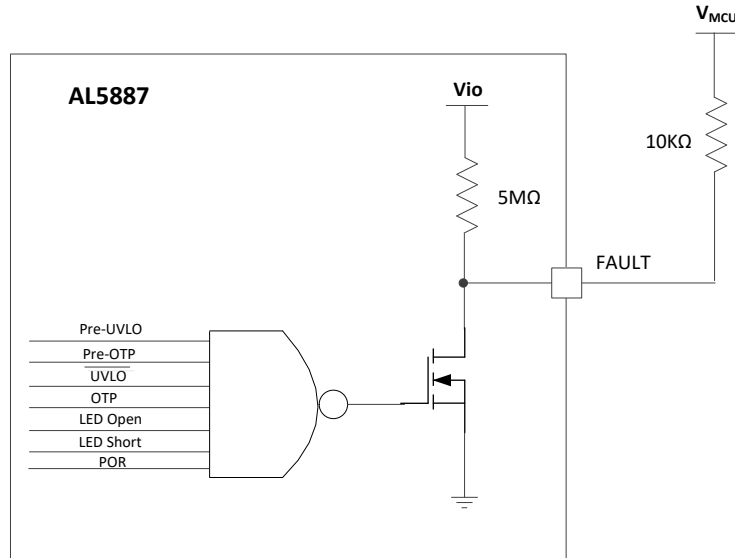

POR\_Mask prevents the POR event from being reported to FAULT pin.

**Functional Description** (continued)

**2.4.8 FAULT Output**

The FAULT pin is a fault indicator pin. It can be used as an interrupt output to master controller in case of any fault. The FAULT pin is an NMOS open-drain output with an internal 5MΩ pull-up resistor, pulled to V<sub>io</sub> and if additionally, this pin can also be pulled up externally to controller supply using a smaller resistor like 10kΩ, as shown in figure below. When one or any of the faults is triggered such as UVLO, OTP, Pre-UVLO, Pre-OTP, channel open, channel short is detected, FAULT pin is pulled low continuously. Once the FAULT pin output is triggered, the controller needs to take necessary action and to deal with the fault and reset the fault flag. AL5887 takes action only for UVLO and OTP faults. For any other fault, AL5887 only reports the fault and controller needs to take the action.

**Figure 10. FAULT Internal Block Diagram**

**2.5 Interface Selection**

Interface selection between SPI and I2C is done using an external pin INT\_SEL. When tied low, I2C is selected while when connected to high, SPI is selected.

**2.6 Digital Communication Enhancements**

Pulling the external pin RSTn high enables the internal digital block. Pulling down for time duration between 1ms to 20ms resets only the digital interface and would keep other register values unaltered. Pulling down for time duration more than 20ms would reset all the registers. There is an internal pull up resistor that would by default pull up this pin to HIGH.

## Functional Description (continued)

### 2.7 Current Setting for all Channels

The maximum global output current for all 36 channels can be adjusted by the external resistor,  $R_{SET}$ , as described below.

$$I_{MAX} = K_{IREF} \times V_{IREF} / R_{SET} \times [ (Max\_Current\_Option/4) + (3/4) ] \quad \dots\dots\dots(1)$$

where,

$I_{MAX}$  = Channel average current, Color Register = FF, Brightness Register = FF

$V_{IREF}$  = 0.7 V

$R_{SET}$  = External dimming resistor (2.1kΩ recommended)

Max\_Current\_Option = 1 (default) or 0, see *Register Map*.

$K_{IREF} = 21 + (N \times 3)$ , is the current multiplication factor which can be programmed using 6-bit global dimming register G5:G0 (Address = 66H), which is analog dimming register and N is the decimal equivalent of G5 G4 G3 G2 G1 G0.

For example, if all global dimming register bits are 0, the N will be decimal equivalent of 100000 which is 32. Hence,  $K_{IREF} = 21 + (32 \times 3) = 117$ .

Using equation (1) above, for  $R_{SET} = 2.1k\Omega$  and Max\_Current\_Option = 1, below is the table that shows  $I_{MAX}$  variation with respect to the global dimming register bits. From Table 3, we can see that the default value = 39mA, minimum value = 7mA and maximum value = 70mA.

**Table 3.  $I_{MAX}$  vs. Global Dimming @  $R_{SET} = 2.1k\Omega$**

G5	G4	G3	G2	G1	G0	$I_{MAX}$ (mA)	$K_{IREF}$
0	0	0	0	0	0	39 (Default)	117 (Default)
0	0	0	0	0	1	40	120
0	0	0	0	1	0	41	123
0	0	0	0	1	1	42	126
		•				•	•
		•				•	•

1	1	1	1	1	0	37	111
1	1	1	1	1	1	38	114

## Functional Description (continued)

Similarly, using equation (1) above, for global dimming register setting of 000000H and Max\_Current\_Option = 1, below is the table that shows I<sub>MAX</sub> variation with respect to the R<sub>SET</sub>.

**Table 4. I<sub>MAX</sub> vs. R<sub>SET</sub> @ G5:G0 = 000000**

R <sub>SET</sub> (kΩ)	I <sub>MAX</sub> (mA)	K <sub>REF</sub>
2.1 (Recommended)	39	117
14.7	5.57	117
36.5	2.24	117

Table 5 shows I<sub>MAX</sub> range using global dimming at different R<sub>SET</sub> values.

**Table 5. I<sub>MAX</sub> vs. Global Dimming Bits @ Various R<sub>SET</sub>**

R <sub>SET</sub> (kΩ)	I <sub>MAX</sub> (mA)		
	Min	Default	Max
2.1 (Recommended)	7	39	70
14.7	1	5.57	10
36.5	0.4	2.24	4

### 2.7.1 Thermal Considerations

As V<sub>INMAX</sub> increases to 5.5V, the voltage on OUT<sub>x</sub> nodes can go as high as 3V for RED LEDs and 2V for GREEN and BLUE LEDs. In such situation if the user configures G0:G5 or R<sub>EXT</sub> for higher currents, the device would get over heated and might hit the thermal shutdown voltage.

Hence the V<sub>IN</sub> and I<sub>OUTx</sub> for the channels should be chosen in such a way that the device junction temperature does not exceed its thermal shutdown temperature. Below is the formula relating the power dissipation and θ<sub>JA</sub> that can be used to avoid device thermal shutdown.

$$T_J = T_A + (\theta_{JA} \times P_{TOTAL})$$

Where,

- T<sub>J</sub> is the junction temperature.
- T<sub>A</sub> is the ambient temperature.
- θ<sub>JA</sub> is the junction to ambient thermal resistance.
- P<sub>TOTAL</sub> is the device's total power dissipation.

Example: If all the 36 channels are turned on and carry the same current I<sub>MAX</sub>, then the device total power dissipation is given by,

$$P_{TOTAL} = (12 \times V_{(OUT0)} \times I_{MAX}) + (12 \times V_{(OUT1)} \times I_{MAX}) + (12 \times V_{(OUT2)} \times I_{MAX})$$

### 2.8 Microcontroller (MCU) Supply

AL5887 can recognize interface logic levels from 1.8V to 5.5V. So MCU interacting with AL5887 can operate in the range 1.8V to 5.5V. However, the information of the supply used by MCU is required to be shared with AL5887 by connecting the MCU supply to V<sub>io</sub> pin of AL5887.

**Functional Description** (continued)

**2.9 Device Functional Modes**

- **INITIALIZATION:** The device enters into INITIALIZATION mode when EN = High. In this mode, all the registers are reset. Entry can also be from any state, if the RESET (register) = FFh or UVLO is active.
- **NORMAL:** The device enters the NORMAL mode when Chip\_EN (register) = 1. I<sub>VIN</sub> is 7mA (typical).
- **POWER SAVE:** The device automatically enters the POWER SAVE mode when Power\_Save\_EN (register) = 1 and all the LEDs are off for a duration of > 30ms. In POWER SAVE mode, analog blocks are disabled to minimize power consumption, but the registers retain the data and keep it available via I2C/SPI. I<sub>VIN</sub> is 25µA (max). In case of any I2C/SPI command to this device, it goes back to the NORMAL mode.
- **SHUTDOWN:** The device enters SHUTDOWN mode from all states on VIN power down or when EN = Low > 25ms. I<sub>VIN</sub> is < 6µA (max).
- **STANDBY:** The device enters the STANDBY mode when Chip\_EN (register bit) = 0. In this mode, all the OUTx are shut down, but the registers retain the data and keep it available via I2C/SPI. STANDBY is the low-power-consumption mode, when all circuit functions are disabled. I<sub>VIN</sub> is 25µA (max).
- **THERMAL SHUTDOWN:** The device automatically enters the THERMAL SHUTDOWN mode when the junction temperature exceeds +160°C (typical). In this mode, all the OUTx outputs are shut down. If the junction temperature decreases below +150°C (typical), the device returns to the NORMAL mode.

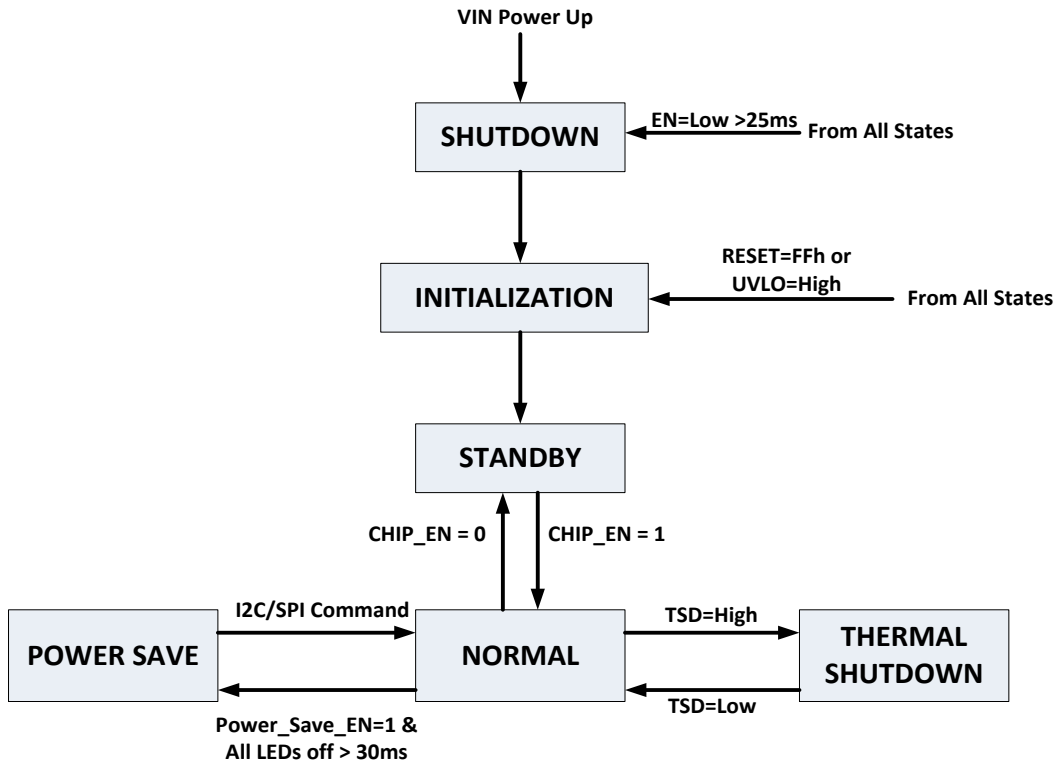

Figure 11. Functional Mode

**Functional Description** (continued)

**3. Programming (SPI)**

**3.1 SPI-Compatible Interface**

The AL5887 is compatible with SPI serial-bus specification and it operates as a slave.

**3.1.1 SPI INITIALIZATION**

Upon the release of power-on-reset (POR), the SPI peripheral in Digital Block waits for the chip selection signal (SPICS\_SCL) from the SPI Controller. The output SPISDA\_ADDR0 of the AL5887 is at high impedance until the reception of an active low on the select line.

The duration of the select line (SPICS\_SCL) should be compliant with the lead and lag time requirements.

Lead time: 1) The time from SPICS\_SCL low to SPISCL\_ADDR1 high.  
2) Least lead time is half clock period.

Lag time: 1) The time from SPISCL\_ADDR1 low to SPICS\_SCL high.  
2) Least lag time is one clock period.

AL5887 is configured to communicate in Mode 0. Data read on rising edge. Clock Polarity in Idle State is Logic Low.

**3.1.2 Write Operation**

A '1' on bit (R/W) of the SPI request frame indicates a write request from the SPI Controller. Bits A6 to A0 provide the address of the register to which the data is to be written. The contents of the frame from bit D7 to D0 is written into the respective register with last positive edge of the SPISCL\_ADDR1 in the current SPI frame.

**Figure 12. SPI Write Transaction**

**3.1.3 Read Operation**

A read request from the SPI Controller is decoded with the read/write enable bit (R/W). A '0' on bit (R/W) of the frame indicates a read request from the Controller.

Bits A6 to A0 provide the address of the register. For a valid address, the 8-bit contents of the respective register is read out. For invalid addresses (out-of range/unused addresses) the response will be a default value (zero). The peripheral responds to the read request one clock cycle later by setting up data on falling edge and Controller reads data on rising edge. The peripheral responds to the read request one clock cycle later by setting up data on falling edge and Controller reads data on rising edge.

**Figure 13. SPI Read Transaction**

**Functional Description** (continued)

**4. Programming (I2C)**

**4.1 I2C Interface**

The I2C-compatible two-wire serial interface provides access to the programmable functions and registers on the device. This protocol uses a two-wire interface for bidirectional communications between the devices connected to the bus. The two interface lines are the serial data line (SDA) and the serial clock line (SCL). Every device on the bus is assigned a unique address and acts as either a master or a slave depending on whether it generates or receives the serial clock, SCL. The SCL and SDA lines should each have a pull-up resistor placed somewhere on the line and remain HIGH even when the bus is idle.

**4.1.1 Data Validity**

The data on SDA line must be stable during the HIGH period of the clock signal (SCL). In other words, the state of the data line can only be changed when the clock signal is LOW.

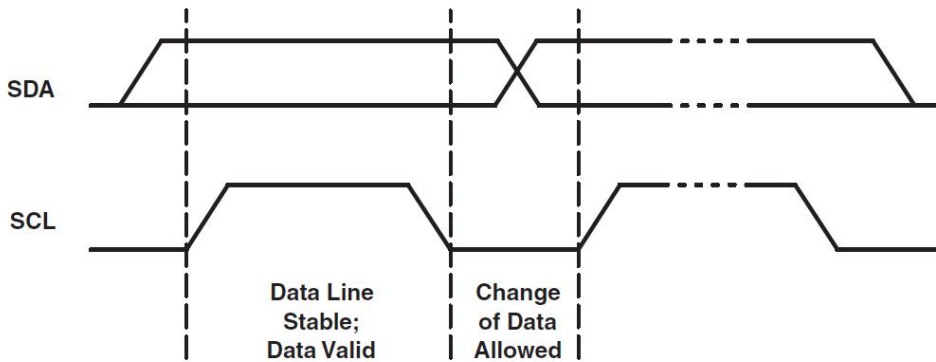

Figure 14. Data Validity

**4.1.2 Start and Stop Conditions**

START and STOP conditions classify the beginning and the end of the data transfer session. A START condition is defined as the SDA signal transitioning from HIGH to LOW while the SCL line is HIGH. A STOP condition is defined as the SDA transitioning from LOW to HIGH while SCL is HIGH. The bus master always generates START and STOP conditions. The bus is considered to be busy after a START condition and free after a STOP condition. During data transmission, the bus master can generate repeated START conditions. First START and repeated START conditions are functionally equivalent.

Figure 15. Start and Stop Conditions

**Functional Description** (continued)

**4.1.3 Transferring Data**

Every byte put on the SDA line must be eight bits long, with the most-significant bit (MSB) being transferred first. Each byte of data must be followed by an acknowledge bit. The acknowledge-related clock pulse is generated by the master. The master releases the SDA line (HIGH) during the acknowledge clock pulse. The device pulls down the SDA line during the 9th clock pulse, signifying an acknowledge. The device generates an acknowledge after each byte has been received.

There is one exception to the acknowledge-after-every-byte rule. When the master is the receiver, it must indicate to the transmitter an end of data by not acknowledging (negative acknowledge) the last byte clocked out of the slave. This negative acknowledge still includes the acknowledge clock pulse (generated by the master), but the SDA line is not pulled down.

After the START condition, the bus master sends a chip address. This address is seven bits long followed by an eighth bit, which is a data direction bit (READ or WRITE). For the eighth bit, a 0 indicates a WRITE, and a 1 indicates a READ. The second byte selects the register to which the data is written. The third byte contains data to write to the selected register.

**Figure 16. Acknowledge and Not Acknowledge on I2C Bus**

**Functional Description** (continued)

**4.1.4 I2C Slave Addressing**

The device slave address is defined by connecting GND or VIO to the SPISDA\_ADDR0 and SPISCL\_ADDR1 pins. A total of 4 independent slave addresses can be realized by combinations when GND or VIO is connected to the SPISDA\_ADDR0 and SPISCL\_ADDR1 pins (see Table 6 and Table 7).

The device responds to a broadcast slave address regardless of the setting of the SPISDA\_ADDR0 and SPISCL\_ADDR1 pins. Global writes to the broadcast address can be used for configuring all devices simultaneously. The device supports global read using a broadcast address; however, the data read is only valid if all devices on the I2C bus contain the same value in the addressed register.

**Table 6. Slave-Address Combinations**

SPISCL_ADDR1	SPISDA_ADDR0	Slave Address	
		Independent	Broadcast
GND	GND	011 0000	001 1100
GND	Vio	011 0001	
Vio	GND	011 0010	
Vio	Vio	011 0011	

**Table 7. Chip Address**

	Slave Address							R/W
	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
<b>Independent</b>	0	1	1	0	0	SPISCL_ADDR1	SPISDA_ADDR0	1 or 0
<b>Broadcast</b>	0	0	1	1	1	0	0	1 or 0

**4.1.5 Control-Register Write Cycle**

- The master device generates a start condition.
- The master device sends the slave address (7 bits) and the data direction bit (R/W = 0).
- The slave device sends an acknowledge signal if the slave address is correct.
- The master device sends the control register address (8 bits).
- The slave device sends an acknowledge signal.
- The master device sends the data byte to be written to the addressed register.
- The slave device sends an acknowledge signal.
- If the master device sends further data bytes, the control register address of the slave is incremented by 1 after the acknowledge signal. To reduce program load time, the device supports address auto incrementation. The register address is incremented after each 8 data bits.
- The write cycle ends when the master device creates a stop condition.

**Figure 17. Write Cycle**

**Functional Description** (continued)

**4.1.6 Control-Register Read Cycle**

- The master device generates a start condition.
- The master device sends the slave address (7 bits) and the data direction bit (R/W = 0).
- The slave device sends an acknowledge signal if the slave address is correct.
- The master device sends the control register address (8 bits).
- The slave device sends an acknowledge signal.
- The master device generates a repeated-start condition.
- The master device sends the slave address (7 bits) and the data direction bit (R/W = 1).
- The slave device sends an acknowledge signal if the slave address is correct.
- The slave device sends the data byte from the addressed register.
- If the master device sends an acknowledge signal, the control-register address is incremented by 1. The slave device sends the data byte from the addressed register. To reduce program load time, the device supports address auto incrementation. The register address is incremented after each 8 data bits.
- The read cycle ends when the master device does not generate an acknowledge signal after a data byte and generates a stop condition.

**Figure 18. Read Cycle**

## Mechanical Data

---

### Package W-QFN6060-52/SWP (Type A1)

- Moisture Sensitivity: Level 3 per J-STD-020
- Terminals: Finish – Matte Tin Plated Leads, Solderable per JESD22-B102 (e3)
- Weight: 0.0091 grams (Approximate)

---

## Design Tools

---

- AL5887 Demo Board
- Emulator
- Demo Board Gerber File for PCB Layout Reference
- PSpice Digital Simulation

2. The Information contained herein is for informational purpose only and is provided only to illustrate the operation of Diodes' products described herein and application examples. Diodes does not assume any liability arising out of the application or use of this document or any product described herein. This document is intended for skilled and technically trained engineering customers and users who design with Diodes' products. Diodes' products may be used to facilitate safety-related applications; however, in all instances customers and users are responsible for (a) selecting the appropriate Diodes products for their applications, (b) evaluating the suitability of Diodes' products for their intended applications, (c) ensuring their applications, which incorporate Diodes' products, comply the applicable legal and regulatory requirements as well as safety and functional-safety related standards, and (d) ensuring they design with appropriate safeguards (including testing, validation, quality control techniques, redundancy, malfunction prevention, and appropriate treatment for aging degradation) to minimize the risks associated with their applications.
3. Diodes assumes no liability for any application-related information, support, assistance or feedback that may be provided by Diodes from time to time. Any customer or user of this document or products described herein will assume all risks and liabilities associated with such use, and will hold Diodes and all companies whose products are represented herein or on Diodes' websites, harmless against all damages and liabilities.
4. Products described herein may be covered by one or more United States, international or foreign patents and pending patent applications. Product names and markings noted herein may also be covered by one or more United States, international or foreign trademarks and trademark applications. Diodes does not convey any license under any of its intellectual property rights or the rights of any third parties (including third parties whose products and services may be described in this document or on Diodes' website) under this document.
5. Diodes' products are provided subject to Diodes' Standard Terms and Conditions of Sale (<https://www.diodes.com/about/company/terms-and-conditions/terms-and-conditions-of-sales/>) or other applicable terms. This document does not alter or expand the applicable warranties provided by Diodes. Diodes does not warrant or accept any liability whatsoever in respect of any products purchased through unauthorized sales channel.
6. Diodes' products and technology may not be used for or incorporated into any products or systems whose manufacture, use or sale is prohibited under any applicable laws and regulations. Should customers or users use Diodes' products in contravention of any applicable laws or regulations, or for any unintended or unauthorized application, customers and users will (a) be solely responsible for any damages, losses or penalties arising in connection therewith or as a result thereof, and (b) indemnify and hold Diodes and its representatives and agents harmless against any and all claims, damages, expenses, and attorney fees arising out of, directly or indirectly, any claim relating to any noncompliance with the applicable laws and regulations, as well as any unintended or unauthorized application.
7. While efforts have been made to ensure the information contained in this document is accurate, complete and current, it may contain technical inaccuracies, omissions and typographical errors. Diodes does not warrant that information contained in this document is error-free and Diodes is under no obligation to update or otherwise correct this information. Notwithstanding the foregoing, Diodes reserves the right to make modifications, enhancements, improvements, corrections or other changes without further notice to this document and any product described herein. This document is written in English but may be translated into multiple languages for reference. Only the English version of this document is the final and determinative format released by Diodes.
8. Any unauthorized copying, modification, distribution, transmission, display or other use of this document (or any portion hereof) is prohibited. Diodes assumes no responsibility for any losses incurred by the customers or users or any third parties arising from any such unauthorized use.
9. This Notice may be periodically updated with the most recent version available at <https://www.diodes.com/about/company/terms-and-conditions/important-notice>
